In fluid dynamics, wind waves, or wind-generated waves, are water surface waves that occur on the free surface of bodies of water. They result from the wind blowing over an area (or fetch) of fluid surface. Waves in the oceans can travel thousands of miles before reaching land.

When directly generated and affected by local winds, a wind wave system is called a wind sea. After the wind ceases to blow, wind waves are called swells. More generally, a swell consists of wind-generated waves that are not - or are hardly - affected by the local wind at that time. They have been generated elsewhere or some time ago.

A theory is initiated for the generation of waves upon a water surface, originally at rest, by a random distribution of normal pressure associated with the onset of a turbulent wind. Correlations between air and water motions are neglected and the water is assumed to be inviscid, so that the motion of the water, starting from rest, is irrotational.

The principal generation forces are driven by the wind, atmospheric pressure gradients, and gravitational attraction. Restoring forces are normally driven by surface tension, gravity, and Coriolis force. From the smallest to the largest, waves can be classified as capillary, ultragravity, gravity, infragravity, long-period, and tidal waves.

Types of Ocean Surface Waves, Wave Classification ...

Regular unidirectional swell. Short waves are waves, generated by the wind that propagate towards the beach. They can be either actively forced by the wind (wind waves - see below) or they can have left their generation area (swell waves - see below). Incident waves are the primary source of energy input to the beach.

This is a disadvantage for wind and solar which generate most of their energy in the summer months. However, this is a competitive advantage for wave energy which produces energy in winter.

Renewables like solar and wind, however, only provide intermittent generation, despite their accounting for about a third of the state's electricity. California has been shuttering its nuclear and natural gas plants that can provide power 24/7 and ramp up when demand surges or the output of renewable sources declines.
